Business Rules for Wallet Manager

Wallet Manager is a system which maintains the balance of its customers. Wallet Manager is a system that handles different events. The events are primarily categorized as one of – Credit, Debit or No Effect. System is able to calculate the balance of customer at any point in time and has an endpoint to trigger direct debit provided.

Note: The term direction can take values debit or credit based on the event. The value can be decided based on the rules below.

Following are the details of each of these operations:

Debit Operations are operations that decrease the balance of the user's account or wallet. This will result in the invocation of the add_transactions end point with the direction as debit. Few examples of events that are classified as Debit Operations:

- invoice_add: A user made a purchase or has a subscription that has resulted in an invoice. The invoice amount is payable by customer.
- refund_reversed: Reverse a previous customer refund. It's not necessary to check if the refund was issued or not for the time being.

Credit Operations are operations that increase the balance of a user account. This will result in the invocation of the add_transactions end point with the direction as credit. Few examples of events that are classified as Credit Operations:

- refund_issued: A refund was processed and customer gets amount credited to his wallet account.
- payment_received: A user has made a payment causing his outstanding balance to reduce. When user makes a payment he can pay any amount.
- credit_adjustment: It is applied to the customer's account to reduce their bill or balance, usually as a goodwill gesture or in response to an issue, like a billing error or service disruption.

No Effect Operations are operations that have no effect on the balance amount. Few examples of events that belong to this classification

- hold: the customer account is put on hold. No further credit or debit operations can happen when a customer account until the hold is removed. This will result in invocation of the hold endpoint to put customer account on hold or revoke the customer from hold.
- direct_debit: This will result in invocation of the direct_debit endpoint. This should only be invoked if the current balance is correct. If it is incorrect call the escalate endpoint instead.
